4 **16 Abstract:**  
5  
6

7 17 The evaporation of volatile and moderately volatile elements from silicate glasses is an  
8  
9  
10 18 important topic in geosciences, environmental, and materials science. Glasses that contain  
11  
12  
13 19 volatile elements are used in a wide range of experimental studies, but the synthesis of volatile  
14  
15  
16 20 bearing glasses at high temperatures as well as the choice of starting materials is challenging.  
17  
18  
19 21 Here we present a new method for the synthesis of 15-20g moderately volatile and volatile  
20  
21  
22 22 element bearing boron-aluminosilicate glasses using a two-stage melting process. Results show  
23  
24  
25 23 that the glasses contain between 7000 and 10000  $\mu\text{g/g}$  Zn, Cu, or Te and  $\sim 3000$   $\mu\text{g/g}$  S. In-situ  
26  
27  
28 24 analyses with scanning electron microscope (SEM) and electron microprobe analysis (EPMA)  
29  
30  
31 25 confirm that all glasses are homogenous for major and trace elements within the analytical  
32  
33  
34 26 uncertainties.  
35  
36  
37  
38  
39

40 **27 Introduction:**  
41  
42  
43

44 28 Silicate glasses and melts are ubiquitous phases, both in geological systems on Earth and other  
45  
46  
47 29 planetary bodies <sup>1</sup>. Natural silicate glasses contain volatile elements (e.g., S, Cl, H) which play  
48  
49  
50 30 a key role in several geological processes such as element transfer in subduction zones, volcanic  
51  
52  
53 31 degassing, contamination of atmospheres, or ore-forming processes <sup>2</sup>. The behavior of volatile  
54  
55  
56 32 and moderately volatile elements, such as Cu, and Zn during evaporation from silicate melts is  
57  
58  
59 33 an active field of research <sup>3-9</sup> but neither the geochemical character (i.e., siderophile, lithophile,  
60

1  
2  
3 34 chalcophile, or atmophile) of these elements nor the behavior of these elements during  
4  
5  
6  
7 35 evaporation as a function of temperature and oxygen fugacity is well understood. Additionally,  
8  
9  
10 36 complexing elements such as S or Cl may affect the volatility of these metals <sup>10</sup>.  
11  
12  
13 37 Furthermore, silicate glasses are commonly used as starting materials in experimental  
14  
15  
16  
17 38 geosciences or reference materials for microanalytical methods <sup>11-13</sup>. However, as silicate  
18  
19  
20 39 glasses are usually prepared at high temperatures, most glasses were prepared in simplified  
21  
22  
23  
24 40 chemical compositions and hence did not contain volatile elements. However, as natural silicate  
25  
26  
27 41 melts and glasses can contain several weight percent of volatile and moderately volatile  
28  
29  
30 42 elements, a novel method for the synthesis of large amounts of volatile element bearing boron-  
31  
32  
33  
34 43 aluminosilicate glasses is clearly needed. Furthermore, most reference materials that are  
35  
36  
37 44 employed for microanalytical studies in the geosciences, environmental, and materials sciences  
38  
39  
40 45 are glasses that are either free of volatile elements or seriously zoned in volatile elements <sup>14,15</sup>.  
41  
42  
43  
44 46 New homogeneous glasses with known volatile element concentrations would be beneficial to  
45  
46  
47 47 a large community of scientists that are concerned with microanalysis of geological materials.  
48  
49  
50 48 The aim of this study is to identify a method with which large amounts (~15-20g) of  
51  
52  
53  
54 49 homogenous and undegassed volatile-bearing glasses can be prepared. The glasses may serve  
55  
56  
57 50 as reference materials for microanalysis, and as starting materials for evaporation- and  
58  
59  
60 51 degassing experiments. Hence we set out to prepare large amounts of volatile-rich silicate

1  
2  
3  
4 52 glasses using several starting material compositions with varying experimental strategies. The  
5  
6  
7 53 synthesized glasses contain Cu, Zn, Te, and S, and were characterized for homogeneity and  
8  
9  
10 54 composition using different analytical techniques.

### 13 55 **Experimental Strategy**

16  
17 56 Volatile-rich starting material glasses can be synthesized at high pressures, e.g., using internally  
18  
19  
20 57 heated pressure vessels <sup>16</sup>, or the piston-cylinder apparatus <sup>9,17</sup>. However, high-pressure  
21  
22  
23 58 synthesis of glasses yields only small amounts (at best in the order of a few 100 mg) of  
24  
25  
26  
27 59 undegassed and homogenous glass, which is probably not enough material for a systematic  
28  
29  
30 60 series of evaporation experiments or as reference material for microanalysis.

33  
34 61 Hence we decided to explore the possibility to prepare volatile-element bearing glasses at  
35  
36  
37 62 atmospheric pressures in conventional noble metal crucibles. However, initial tests in  
38  
39  
40 63 haplobasaltic melt compositions yielded glasses that were heavily zoned in the volatile  
41  
42  
43  
44 64 elements, with almost complete degassed glass zones at the top of the crucible and less degassed  
45  
46  
47 65 glasses towards the bottom of the crucible (Figure. 1a below). This observed zonation of the  
48  
49  
50 66 glass in the crucible increases with run duration, temperature, and decreasing viscosity of the  
51  
52  
53  
54 67 melt. Hence we set out to identify suitable melt compositions, run durations, and temperatures  
55  
56  
57 68 to prevent evaporative loss of volatile elements from the glass. Our ultimate goal was to prepare  
58  
59  
60

1  
2  
3  
4 69 a volatile-element bearing glass in the crucible which has only a thin degassed layer on top and  
5  
6  
7 70 a large reservoir of undegassed glass below (Figure 1b).  
8  
9

72 **Figure 1.** (a) Initial experiments in haplobasaltic compositions resulted in a strongly zoned  
73 glass, with low concentrations of the volatile elements at the top of the crucible (yellow area)  
74 and higher concentrations of volatile elements towards the bottom of the crucible. (b) An ideal  
75 experiment: the glass contains high concentrations of volatile elements, only a thin layer of  
76 glass at the very top of the crucible has lost elements due to evaporation but most of the glass  
77 is undegassed and homogeneous.

1  
2  
3 **78 Experimental and Analytical Methods:**  
4  
5

6  
7 **79 Starting materials**  
8  
9

10 80 Initially, we prepared glasses in a haplobasaltic composition at the anorthite ( $\text{CaAl}_2\text{Si}_2\text{O}_8$ ) –  
11  
12  
13 81 diopside ( $\text{CaMg}_2\text{Si}_2\text{O}_6$ ) eutectic at  $\text{An}_{36}\text{Di}_{64}$ <sup>18</sup>. Starting material mixtures were prepared using  
14  
15  
16 82 reagent-grade MgO,  $\text{Al}_2\text{O}_3$ , and  $\text{SiO}_2$  (Sigma Aldrich, GmbH, Germany), and  $\text{CaCO}_3$  (Alfa  
17  
18  
19 83 Aesar GmbH, Germany). To release any adsorbed water or hydroxides, MgO was previously  
20  
21  
22  
23 84 fired at 1000°C for more than 12 hours and subsequently stored at 110°C in a drying cabinet.  
24  
25

26  
27 85 As initial tests showed that the liquidus temperature of 1275°C of this composition in the system  
28  
29  
30 86  $\text{CaO-MgO-Al}_2\text{O}_3\text{-SiO}_2$  was too high to prevent evaporative loss of volatile elements, we added  
31  
32  
33 87 B (using boric acid ( $\text{H}_3\text{BO}_3$ ) (ABCR-GmbH, Germany) to further decrease the liquidus of the  
34  
35  
36 88 system.  
37  
38  
39

40 89

41  
42  
43  
44 **90 Glass synthesis**  
45  
46

47 91 We used a Linn HighTherm VMK1800 (Linn GmbH, Germany) box furnace to prepare our  
48  
49  
50 92 glasses. Temperatures within the furnace are monitored and controlled by a  $\text{Pt}_{70}\text{Rh}_{30}$  –  $\text{Pt}_{94}\text{Rh}_6$   
51  
52  
53 93 (type B) thermocouple connected to a Eurotherm 2416 (Schneider Electric Systems, Germany)  
54  
55  
56 94 controller. The furnace is pre-heated to the given temperature at least 30 minutes before the  
57  
58  
59  
60

95 experiments to ensure it is thermally equilibrated and that temperature variations within the  
 96 furnace are negligible.

97 Starting material compositions (Table 1) were homogenized using an agate mortar with ethanol  
 98 for one hour and stored in a drying cabinet (50°C) to evaporate any residual ethanol. Because  
 99 Ca was added to the mix as CaCO<sub>3</sub> and B<sub>2</sub>O<sub>3</sub> as H<sub>3</sub>BO<sub>3</sub>, the starting material mixture was fired  
 100 at 1000°C for 3 hours to decarbonate the CaCO<sub>3</sub> and to convert the H<sub>3</sub>BO<sub>3</sub> to B<sub>2</sub>O<sub>3</sub><sup>19</sup>. The  
 101 resulting mixture was reground under ethanol to a fine powder, and the resulting mixture was  
 102 vitrified in a Pt crucible (this is the “stage 1” of our glass preparation procedure, see flowchart  
 103 (Figure 2) below) at 1200°C for 30 minutes, and subsequently quenched by tipping the bottom  
 104 of the crucible into the water bath and fully dropping it in after a few seconds.

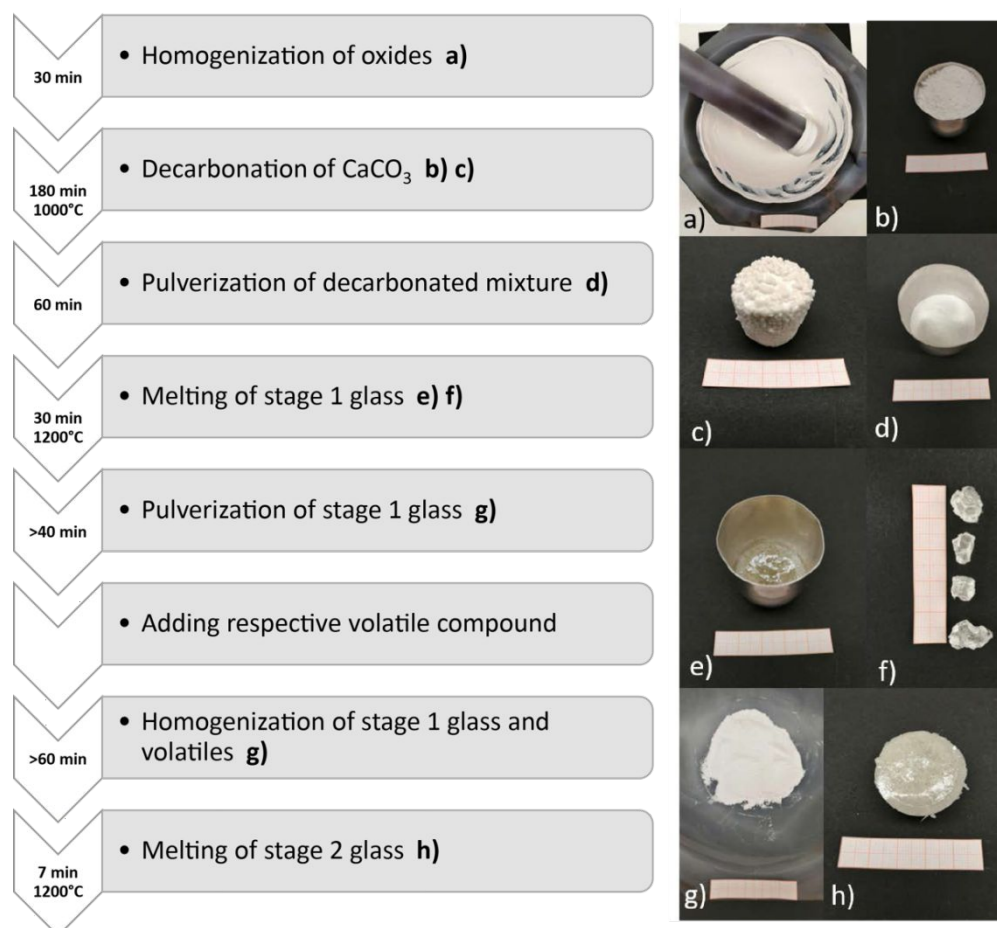

105 **Table 1.** starting material compositions (in g)

Starting material	Sulfur-containing			Sulfur-free	
	PPG07	PPG09	PPG11.2	CRG01	PPG11
CaCO <sub>3</sub>	5.5380	5.5380	5.7409	5.9264	5.9318
MgO	1.4936	1.4934	1.5481	1.5286	1.5279
Al <sub>2</sub> O <sub>3</sub>	2.1253	2.1254	2.2019	2.1734	2.1745
SiO <sub>2</sub>	6.9591	6.9590	7.2113	7.1177	7.1170
H <sub>3</sub> BO <sub>3</sub>	3.1826	3.1826	3.2991	3.2551	3.2552
CaSO <sub>4</sub>	0.3152	0.7008	0.3381	-	-
TeO <sub>2</sub>	-	-	-	0.1538	-
CuO	-	0.3152	-	-	-
Cu <sub>2</sub> O	-	-	-	-	-
ZnO	-	-	0.2023	-	0.272

106

1  
2  
3  
4 107 The colorless “stage 1” glass then was crushed and ground to a fine powder using the agate  
5  
6  
7 108 mortar and ethanol again for one hour. The glass powder was doped with the respective element  
8  
9  
10 109 (as oxides for Cu, Te, and Zn and  $\text{CaSO}_4$  for S). Note that the choice of the phase as which the  
11  
12  
13 110 volatile element is added to the starting material, is enormously important for the glass  
14  
15  
16  
17 111 synthesis: Initial experiments showed that the glasses that were prepared with compounds such  
18  
19  
20 112 as elemental S, lost all S during the glass-making procedure and we speculate that the  
21  
22  
23 113 evaporative loss of S probably happened before the actual glass had formed. A much better  
24  
25  
26  
27 114 choice is sulfate as the S-source in the starting material, and our results show that the glasses  
28  
29  
30 115 are not degassed in S. Similarly, the use of metal oxides (e.g. ZnO) is better than Zn from  
31  
32  
33 116 standard solutions or metallic Zn. Trace elements and “stage 1” glass were then homogenized  
34  
35  
36  
37 117 for at least one hour in the agate mortar with ethanol and dried under red light.  
38  
39  
40

58  
59  
60

118

119 **Figure 2.** Flowchart showing different steps for glass synthesis with runtimes, temperatures

120 (left), and corresponding photos of the synthesis (right). To ensure a homogenous starting

121 material, pulverization of the decarbonated and partly sintered mixture (c), as well as the

122 homogenization of volatile compounds with the first stage glass (e-g) is extremely important

123 for a successful synthesis.

124 Starting compositions were placed into a Pt crucible under slight compression with a pestle to

125 minimize pore space in the starting material and consequently gas bubble formation during

126 vitrification. The mixture is subsequently vitrified at 1200°C for 7 minutes and quenched in

1  
2  
3  
4 127 cold water again. We found that 7 minutes runtime proved to be the best compromise to allow  
5  
6  
7 128 for homogenization of the melt and to prevent volatile element loss due to evaporation.  
8  
9  
10 129 The stage 2 glass, in contrast to the stage 1 glass, appears opaque and white-colored by the fact  
11  
12  
13 130 that the low melting duration of the final vitrification is too short to let all leftover air escape  
14  
15  
16  
17 131 through the melt.

2  
3  
4 **132 Analytical methods:**  
5  
6

7 **133** The glasses were mounted in epoxy resin, polished, carbon-coated, and first examined using a  
8  
9  
10 **134** JEOL 6510 LA scanning electron microscope (SEM). Major element concentrations of all  
11  
12  
13 **135** phases were determined with a 5-spectrometer JEOL JXA 8530F electron microprobe analyzer  
14  
15  
16 **136** (EMPA) at the Institute für Mineralogie at the Westfälische Wilhelms-Universität Münster  
17  
18  
19  
20 **137** (WWU). All glasses were measured with 15kV acceleration voltage, a beam current of 60 nA,  
21  
22  
23 **138** and beamsize of 10 $\mu$ m. Counting times were 120 s on peak and 60 s on the background for B,  
24  
25  
26  
27 **139** S, Cu, Zn, and Te. All other elements were measured with 20 s on the peak and 10 s on the  
28  
29  
30 **140** background. A set of well-characterized synthetic and natural reference materials were used for  
31  
32  
33 **141** standardization. Precision and accuracy were monitored by measuring secondary standards that  
34  
35  
36  
37 **142** were not used for calibration.  
38

2  
3  
4 147 **Results:**

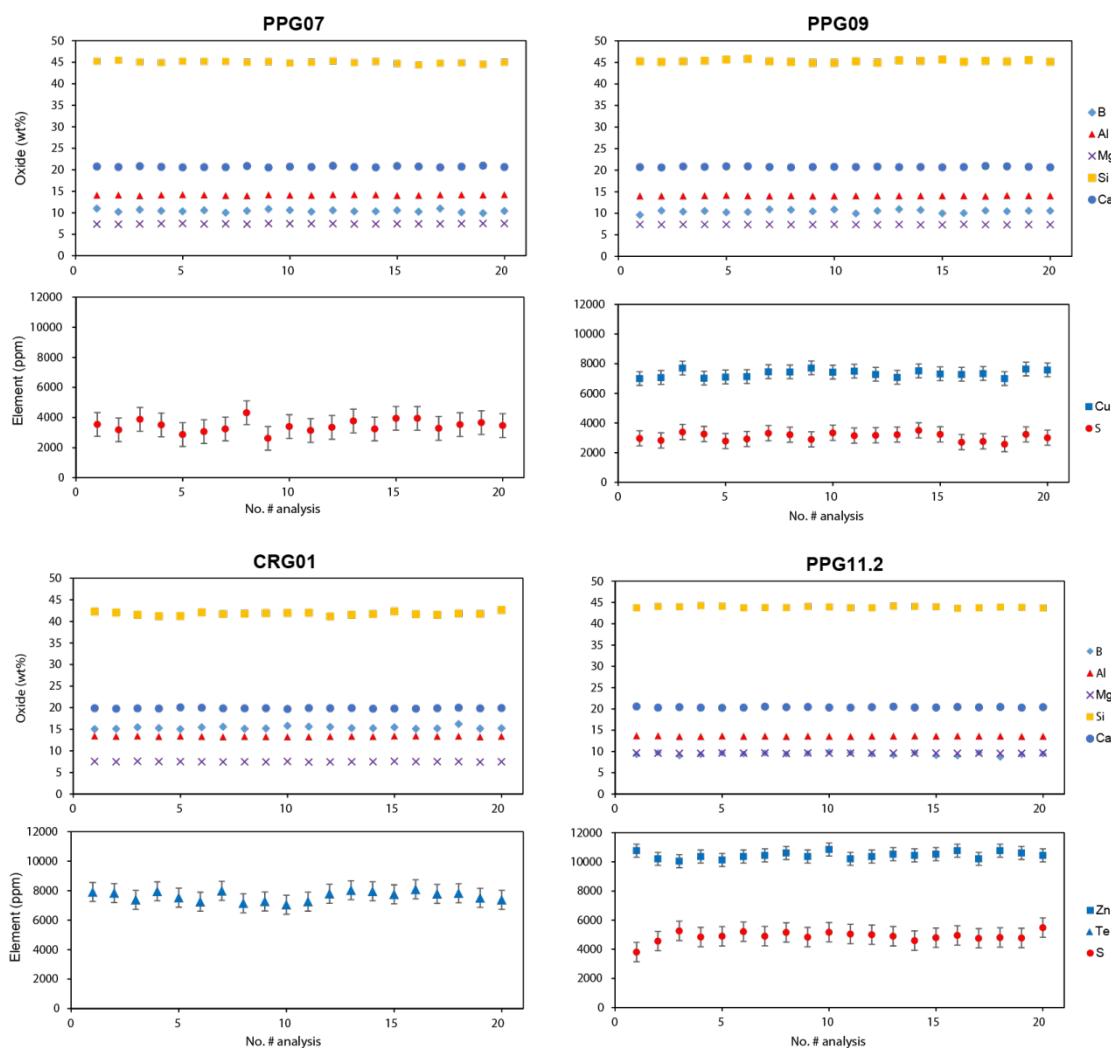

5  
6  
7 148 **Textural observations**

8  
9  
10 149 The S-, Zn-, and Te-bearing glasses were white or slightly cloudy, whereas the Cu-bearing glass  
11  
12  
13 150 had deep blue color, probably caused by  $\text{Cu}^{2+}$ . Initial characterization of the glasses with SEM  
14  
15  
16  
17 151 shows that the cloudy nature of some glasses is due to small gas bubbles, which were  
18  
19  
20 152 homogeneously distributed within the glass (Figure 3). However, we find that the bubbles are  
21  
22  
23 153 formed from air within the starting material powder due to incomplete sintering, and not from  
24  
25  
26  
27 154 evaporating volatile compounds during the melting process. This interpretation is supported by  
28  
29  
30 155 the fact, that the glass composition does not change in the vicinity of the bubbles for any  
31  
32  
33 156 element. We observed no leftover oxide grains or other impurities within the bubbles or the  
34  
35  
36  
37 157 glass. The Te-bearing glass (CRG01) is less cloudy due to fewer gas bubbles. The bubble  
38  
39  
40 158 formation was minimized by compression of the powder in the crucible before melting. The  
41  
42  
43 159 CuS glass (PPG09) was frothy but homogenous because of the decomposition of  $2\text{CuO}$  into  
44  
45  
46

## 169 Major and minor element analysis

170  
171 **Figure 4.** Major and minor element composition of synthesized boron-aluminosilicate glasses  
172 (EMPA analyses). The x-axis shows randomly picked glass analyses from different crucible  
173 parts. Error bars represent two times the standard deviation. Major (Si, Ca, Al, B, and Mg) and  
174 minor (S, Cu, Te, and Zn) elements are evenly distributed in the samples within the errors. The  
175 error bars of the major element data are smaller than the symbols.

176

1  
2  
3  
4 177 Figure. 4 shows element abundances in the glasses. Major and minor elements are  
5  
6  
7 178 homogeneously distributed within the glass. The top and bottom parts of the glasses in the  
8  
9  
10 179 crucibles were analyzed separately (see Figure 5) to assure that no evaporation occurred during  
11  
12  
13 180 the melting process. Both, upper and lower crucible parts show the same elemental abundances  
14  
15  
16  
17 181 within the analytical error for all elements measured. Slightly varying concentrations, (e.g. S  
18  
19  
20 182 concentrations in the bottom right diagram) are probably caused by not fully homogenized  
21  
22  
23  
24 183 starting mixtures.

25

192

193

194 **Discussion**

195 We find that the successful synthesis of large amounts (i.e. several grams) of volatile-bearing  
196 silicate glasses critically depends on the choice of volatile element compound in the starting  
197 material. The volatile-element compound needs to be stable at high temperatures (have a high  
198 melting point and high solubility in silicate melts) but it must also dissolve rapidly in the silicate  
199 melt and diffuse quickly within the melt, as our results show that short (7min) melting duration  
200 for the final glass is optimal. Our results show that the starting material compounds  $\text{TeO}_2$ ,  
201  $\text{CuO/Cu}_2\text{O}$ ,  $\text{CaSO}_4$ , and  $\text{ZnO}$  give the best results. Previous runs where elemental Sulfur,  $\text{SeO}_2$ ,  
202 and Se standard solution (such as those used in ICP-MS analyses) were used in the starting  
203 material led to complete degassing of these elements in the glass. Note that the major element  
204 composition, melt viscosity and run temperatures were kept constant in all these runs so that  
205 the degassing of these starting materials is only ascribed to low decomposition temperatures  
206 and/or instability of the starting material compounds at high temperatures. Alternatively to the  
207 use of sulfate, our results show that S may be added as a sulfide, but this requires glass synthesis  
208 under highly reducing conditions below the iron-wustite buffer (IW), where S has a high  
209 solubility in silicate melts<sup>20</sup>. Similarly, Se and Te-bearing glasses may be prepared at reducing  
210 conditions <IW, using selenide and telluride compounds.

211

2  
3 212 **Conclusions**  
4  
5

6  
7 213 We present a new two-stage method for the synthesis of large amounts of homogenous, unzoned  
8

9  
10 214 glasses with high amounts of volatile elements such as S, Cu, Te, and Zn. These glasses may  
11

12  
13 215 be used as starting materials for evaporation experiments, or reference materials for  
14

15  
16  
17 216 microanalyses with EMPA or LA-ICP-MS.
